Outline

- Revision of CDT basics
- The transfer matrix idea and measurement
- Transfer matrix in 'C' (de Sitter) phase
- Transfer matrix in 'A' (uncorrelated) phase
- Transfer matrix in 'B' (collapsed) phase
- Conclusions and prospects

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

- **Causal Dynamical Triangulations (CDT)** is a non-perturbative approach to Quantum Gravity based on the path integral

$$Z = \int_{\text{Geom}} D[g] \exp(iS_{HE}[g])$$

- Regularization of Z is done by summing over all **causal triangulations** T constructed from 4-d simplices

$$Z = \sum_T \frac{1}{C_T} \exp(i\tilde{S}_R[T])$$

- We assume a **global time foliation** S^1 and **fixed spatial topology** $S^3 \Rightarrow$ resulting space-time $S^1 \times S^3$ can be built from two types of **simplices**

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

■ The Einstein-Hilbert action:

$$S_{HE} = \frac{1}{16\pi G} \int dt \int d^3x \sqrt{-g} (R - 2\Lambda)$$

- G – Newton's constant
- g – metric determinant
- R – curvature scalar
- Λ – cosmological constant

■ is regularized by the Regge action where curvature R is determined by the deficit angle „around” 2-d triangles

$$\tilde{S}_R = i \left[\underbrace{-K_0}_{\substack{\uparrow \\ l/G}} N_0 + \underbrace{K_4}_{\substack{\uparrow \\ \Lambda}} N_4 + \underbrace{\Delta}_{\substack{\uparrow \\ \alpha}} \left(N_4^{(4,1)} - 6N_0 \right) \right] = iS_R$$

$\alpha \ (l_t^2 = -\alpha l_s^2)$

- N_0 – # of vertices
- N_4 – # of 4-simplices
- $N_4^{(4,1)}$ – # of (4,1) & (1,4) simplices

■ After Wick rotation: $\alpha \rightarrow -\alpha$ ($|\alpha| > 7/12$) S_R is purely real:

$$Z = \sum_T \frac{1}{C_T} \exp(i\tilde{S}_R[T]) = \sum_T \frac{1}{C_T} \exp(-S_R[T]) \quad \rightarrow \quad \text{random geometry system}$$

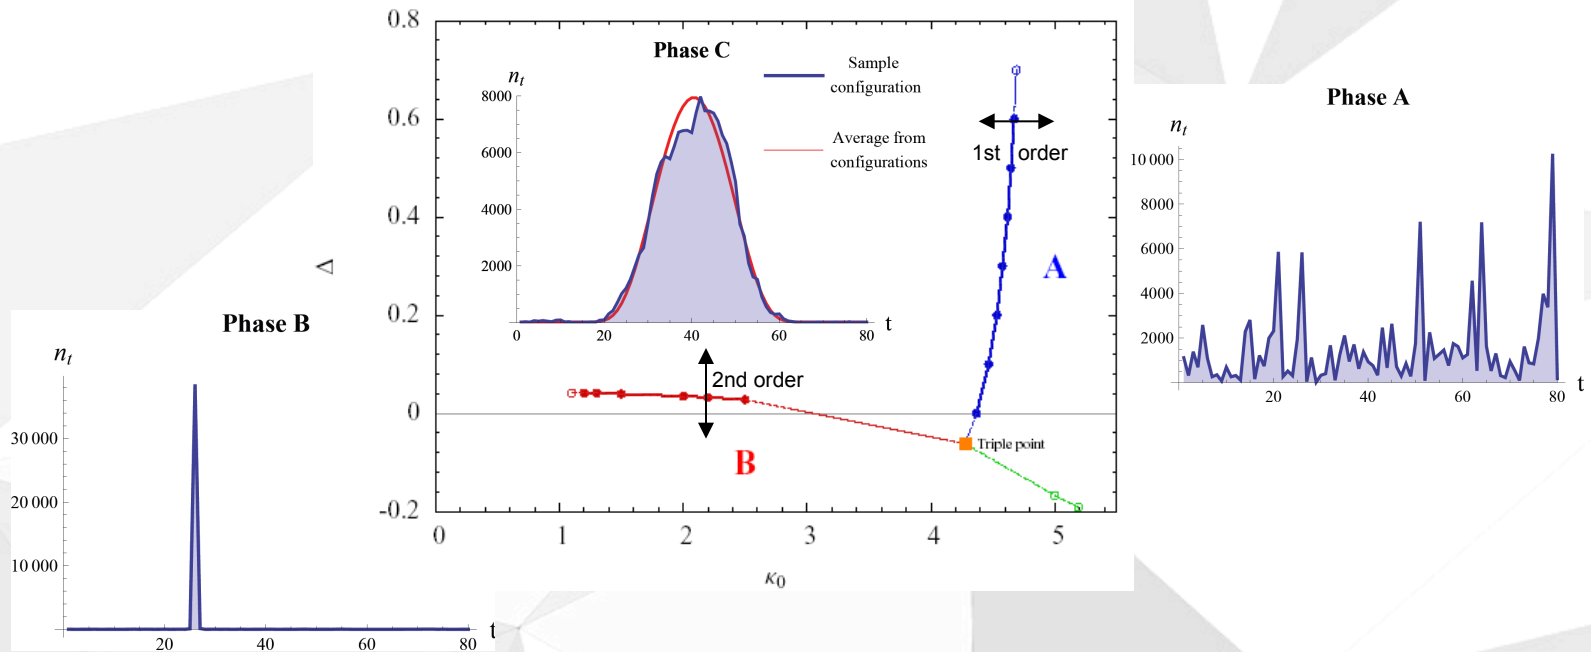

Revision of CDT basics

The transfer matrix idea and measurement
 Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase
 Transfer matrix in 'B' (collapsed) phase
 Conclusions and prospects

$$S_R = -K_0 N_0 + K_4 N_4 + \Delta \left(N_4^{(4,1)} - 6N_0 \right)$$

- Depending on the values of bare couplings K_0 and Δ ($K_4 \approx K_4^{crit}$) **three phases** emerge

Revision of CDT basics

The transfer matrix idea and measurement
Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase
Transfer matrix in 'B' (collapsed) phase
Conclusions and prospects

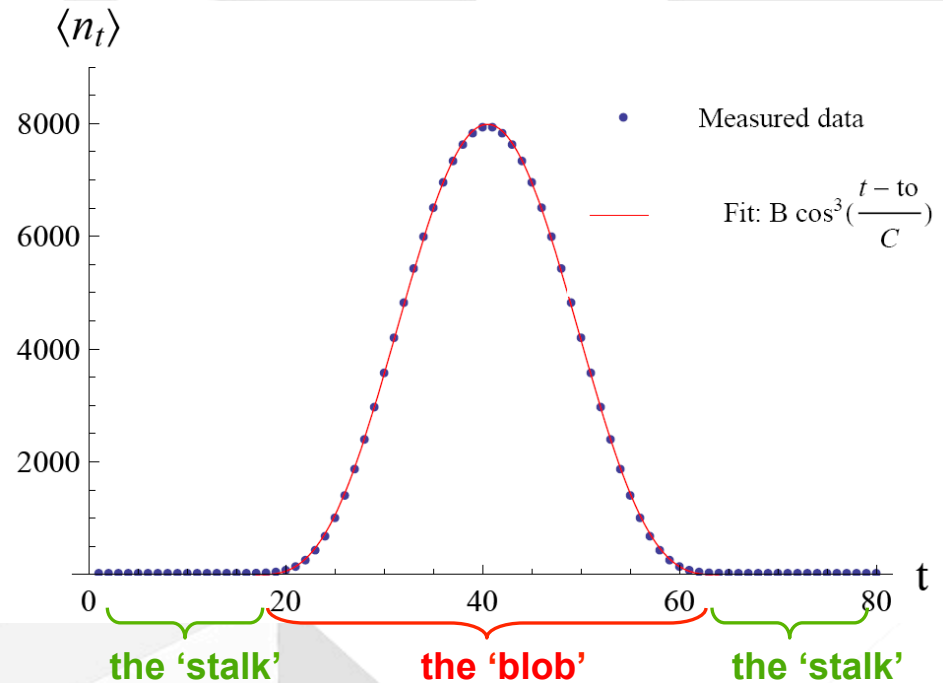

■ In phase 'C' the dynamically generated semi-classical background ...

spatial volume at time t: $n_t \equiv N_4^{(4,1)}(t)$

$$\langle n_t \rangle = \frac{3}{4} \tilde{V}_4 \frac{1}{\tilde{A} \tilde{V}_4^{1/4}} \cos^3 \left(\frac{t - t_0}{\tilde{A} \tilde{V}_4^{1/4}} \right)$$

$$\sqrt{g_{tt}} V_3(t) = \frac{3}{4} V_4 \frac{1}{A V_4^{1/4}} \cos^3 \left(\frac{t - t_0}{A V_4^{1/4}} \right)$$

■ The solution (in the 'blob') is consistent with the Euclidean (Wick's rotation) de Sitter Universe (no matter, positive cosmological const.)

Revision of CDT basics

The transfer matrix idea and measurement
Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

- ... and quantum fluctuations are governed by the action:

$$S = \frac{1}{24\pi G} \int dt \sqrt{g_{tt}} \left(\frac{g^{tt} \dot{V}_3(t)^2}{V_3(t)} + \mu V_3(t)^{1/3} - \lambda V_3(t) \right)$$

□ $\mu = 9 \left(\frac{3}{4} \right)^{2/3} A^{-8/3}$ □ $\lambda = 9 V_4^{-1/2} A^{-2}$

- This is the (Euclidean) **minisuperspace** (MS) action obtained from S_{HE} for the maximally symmetric metric: $ds^2 = g_{tt} dt^2 + a^2(t) d\Omega_3^2 \Rightarrow V_3(t) \propto a^3(t)$
- **Analysis of the effective propagator (vol-vol correlations)** \Rightarrow effective action in the phase 'C' is a discretization of the MS action:

$$S_{dis} = \frac{1}{\Gamma} \sum_t \left(\frac{(n_{t+1} - n_t)^2}{n_{t+1} + n_t} + \tilde{\mu} n_t^{1/3} - \tilde{\lambda} n_t + O(n_t^{-1/3}) \right)$$

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

Transfer Matrix Motivation:

- The large vol. range in phase 'C' is described by the MS effective action:
 - How good is this description ?
 - Can we measure the effective action directly (not only vol-vol correlations) ?
- How to describe the behavior of the small volume range ?
 - Relatively large quantum fluctuations
 - Small volume discretization effects
 - 'Cleaning' of discretization artifacts might lead to discovery of some non-trivial corrections
- Can we analyze the effective action in other phases ?
- Can we say something more about the dynamics of phase transitions?

$$S_{blob} = \sum_t \frac{1}{\Gamma} \left(\frac{(n_{t+1} - n_t)^2}{n_{t+1} + n_t} + \tilde{\mu} n_t^{1/3} - \tilde{\lambda} n_t \right) = \sum_t L_{blob} [n_t, n_{t+1}]$$

$$\langle n_t | M_{blob} | n_{t+1} \rangle = \exp(-L_{blob} [n_t, n_{t+1}])$$

$$Z_{blob} = \sum_{n_1 \dots n_t \dots n_T} \exp(-S_{blob}) = \text{Tr} (M_{blob}^T)$$

Assumptions:

- we consider only effective aggregate 'states' $|n_t\rangle$
- the effective interaction is only between neighboring time slices
- description by the transfer matrix is also viable in other phases
- time translation symmetry $\Rightarrow M$ ~~(\times)~~
- time reflection symmetry $\Rightarrow \langle n_t | M | n_{t+1} \rangle = \langle n_{t+1} | M | n_t \rangle$

$$Z = \sum_{n_1 \dots n_t \dots n_T} \prod_{t=1}^T \langle n_t | M | n_{t+1} \rangle = \text{Tr}(M^T)$$

- We use measured 2-point probability distribution in systems with $T=2$ time slices...

$$P_2(n_1, n_2) = \frac{1}{Z} \langle n_1 | M | n_2 \rangle^2$$

- ...to determine transfer matrix elements:

$$\langle n | M | m \rangle = N \sqrt{P_2(n_1 = n, n_2 = m)}$$

- We explicitly symmetrize: $\langle n | M | m \rangle = \langle m | M | n \rangle$

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

'C' ('de Sitter') phase

- The transfer matrix in phase 'C' is measured and fitted with MS action:

$$\langle n | M | m \rangle = N e^{-L_{eff}[n,m]}$$

$$L_{eff}[n,m] = \frac{1}{\Gamma} \left\{ \frac{(n-m)^2}{n+m-2n_o} + \mu \left(\frac{n+m}{2} \right)^{1/3} - \lambda \left(\frac{n+m}{2} \right) \right\}$$

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

■ The kinetic term ...

$$\langle n | M | m \rangle = N e^{-\frac{1}{\Gamma} \left[\frac{(n-m)^2}{n+m-2n_0} + \mu \left(\frac{n+m}{2} \right)^{1/3} - \lambda \left(\frac{n+m}{2} \right) \right]}$$

$k[n+m] = \Gamma (n+m-2n_0)$

□ Gaussian behaviour for $n+m=s$:

$$\langle n | M | s-n \rangle = \tilde{N}[s] \exp \left\{ -\frac{(2n-s)^2}{k[s]} \right\}$$

- ... and the potential term can be analyzed in detail

$$\langle n | M | m \rangle = Ne^{-\frac{1}{\Gamma} \left\{ \frac{(n-m)^2}{n+m-2n_0} + \mu \left(\frac{n+m}{2} \right)^{1/3} - \lambda \left(\frac{n+m}{2} \right) \right\}}$$

- For $n=m$:

$$\log \langle n | M | n \rangle = -\frac{1}{\Gamma} (\mu n^{1/3} - \lambda n) + \alpha$$

- The fits agree with the previous method based on the covariance matrix *

$$\langle n | M | m \rangle = N e^{-\frac{1}{\Gamma} \left\{ \frac{(n-m)^2}{n+m-2n_0} + \mu \left(\frac{n+m}{2} \right)^{1/3} - \lambda \left(\frac{n+m}{2} \right) \right\}}$$

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

- The transfer matrix gives access to the effective action in the 'stalk' (small volumes) range:

$$\langle n | M | m \rangle = N e^{-L_{\text{eff}}[n,m]}$$

- Discretization effects (split into three families of states) makes analytical modeling difficult

- If we average over these three families M becomes smooth

- The effective action for the stalk is basically the same as for the 'blob' *

$$S_{eff}^{stalk} = \sum_t \frac{1}{\Gamma} \left\{ \frac{(n_t - n_{t+1})^2}{n_t + n_{t+1} - 2n_0} + \mu \left(\frac{n_t + n_{t+1}}{2} \right)^{1/3} - \lambda \left(\frac{n_t + n_{t+1}}{2} \right)^{1/3} + \delta \left(\frac{n_t + n_{t+1}}{2} \right)^{-\rho} \right\}$$

small volume correction

Parameter	Stalk	Blob
Γ	27.2 ± 0.1	$25.7 - 26.2$

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

'A' ('uncorrelated') phase

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

- The kinetic term $\langle n | M | s - n \rangle$ looks anti-gaussian on the first sight ...
- Is it possible that we observe a signature change in large Γ regime?

$$L_C[n, m] = \frac{1}{\Gamma} \frac{(n - m)^2}{n + m} + v_C[n + m]$$

$$L_A[n, m] = -\frac{1}{\Gamma} \frac{(n - m)^2}{k[n + m]} + v_A[n + m]$$

- It looks that $k[n + m]$ is no longer linear, it fits well to:

$$k[n + m] = k_0 (n + m)^{2-\alpha}$$

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

- ... but if the kinetic term vanishes as expected and we expand L_A in $s=n+m$ & $d=n-m$ we recover the effective anti-gaussian behaviour if $\alpha < 1$

$$L_A[n, m] = \mu(n^\alpha + m^\alpha) + \lambda(n + m) = -\frac{\mu\alpha(1-\alpha)}{2^\alpha} \frac{(n-m)^2}{(n+m)^{2-\alpha}} + v_A[n+m] + o(d/s^4)$$

- L_A fits very well to measured potential (diagonal) term $\langle n|M|n \rangle$

$$L_A[n, m] = \mu(n^\alpha + m^\alpha) + \lambda(n + m)$$

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

'B' ('collapsed') phase

- The kinetic term $\langle n | M | s - n \rangle$ depends strongly on $s = n + m$:

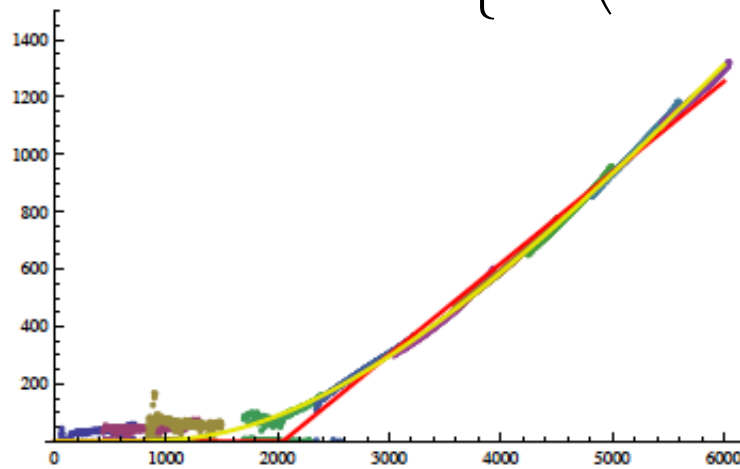

- for $s < s_b$ it fits well to the single gaussian (as in the phase 'C')

- for $s > s_b$ the cross-diagonal splits into sum of two gaussians

$$\langle n | M | s - n \rangle = N[s] \left\{ \exp \left(- \frac{((m - n - c[s]))^2}{k[s]} \right) + \exp \left(- \frac{((m - n + c[s]))^2}{k[s]} \right) \right\}$$

$$\langle n | M | s - n \rangle = N[s] \left\{ \exp \left(- \frac{((m - n - c[s])^2)}{k[s]} \right) + \exp \left(- \frac{((m - n + c[s])^2)}{k[s]} \right) \right\}$$

- $c[s]$ is well fitted by:

$$c[s] \approx \max \left[0, c_0 (s - s_b) \right]$$

- $k[s]$ is linear (as in the phase 'C'):

$$k[s] = \Gamma (s - 2n_0)$$

$$\langle n | M | m \rangle = N[n+m] \left[\exp \left(- \frac{\left((m-n - [c_0(n+m-s_b)]_+ \right)^2}{\Gamma(n+m-2n_0)} \right) + \exp \left(- \frac{\left((m-n + [c_0(n+m-s_b)]_+ \right)^2}{\Gamma(n+m-2n_0)} \right) \right]$$

- This is measured in a given point in the bare coupling constants space (K_0, Δ, K_4)

- But inside the phase 'B': K_4^{crit} is volume dependent ...

$$K_4^{crit} = K_4^\infty - K \cdot s^{-\gamma}$$

- ...and we are interested in large volume behaviour (where $K_4 \uparrow$):

$$S_b = const, \quad c_0 \uparrow$$

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

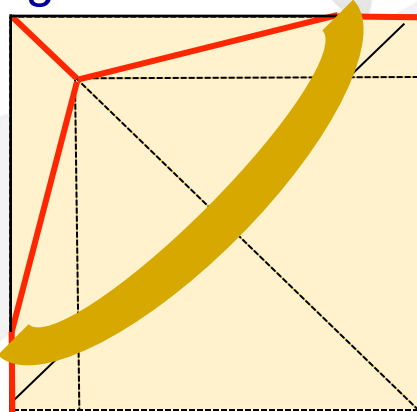

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

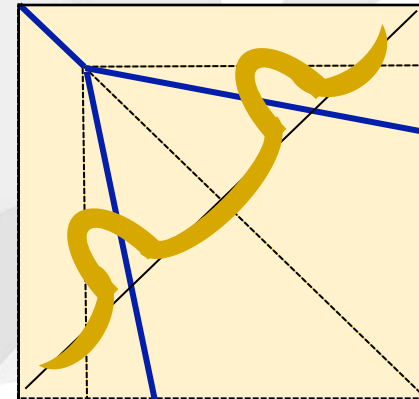

Conclusions and prospects

$$\langle n | M | m \rangle = N[n+m] \left[\exp \left(- \frac{\left((m-n - [c_0(n+m-s_b)]_+)^2 \right)}{\Gamma(n+m-2n_0)} \right) + \exp \left(- \frac{\left((m-n + [c_0(n+m-s_b)]_+)^2 \right)}{\Gamma(n+m-2n_0)} \right) \right]$$

- The limiting behaviour of the system may differ depending on $c_0(K_4^\infty)$

- If $c_0(K_4^\infty) > \sqrt{2}/2$ the effective kinetic term for large vol. looks like "anti-gaussian" and we get generic 'B' phase configuration

- If $c_0(K_4^\infty) < \sqrt{2}/2$ "double gaussian" behaviour persists even for large vol. and typical configuration may mimic 'C' phase blob structure

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in ‘C’ (de Sitter) phase

Transfer matrix in ‘A’ (uncorrelated) phase

Transfer matrix in ‘B’ (collapsed) phase

Conclusions and prospects

$$\langle n | M | m \rangle = N[n+m] \left[\exp \left(- \frac{\left((m-n - [c_0(n+m - s_b)]_+)^2 \right)}{\Gamma(n+m - 2n_0)} \right) + \exp \left(- \frac{\left((m-n + [c_0(n+m - s_b)]_+)^2 \right)}{\Gamma(n+m - 2n_0)} \right) \right]$$

- After crossing B-C phase transition we should regain MS action ($s_b \rightarrow \infty$)

- But it happens for Δ much bigger then suggested by previous phase transitions studies !!!

- It indicates that a newly discovered “bifurcation” phase may exist in CDT

$$\langle n | M | m \rangle = N[n+m] \left[\exp \left(- \frac{\left((m-n - [c_0(n+m - s_b)]_+)^2 \right)}{\Gamma(n+m - 2n_0)} \right) + \exp \left(- \frac{\left((m-n + [c_0(n+m - s_b)]_+)^2 \right)}{\Gamma(n+m - 2n_0)} \right) \right]$$

- Generic configurations in the “bifurcation phase” may resemble ‘C’ phase structure but they should have different scaling properties

- Typical scaling inside the ‘C’ phase with Hausdorff dimension 4 ...
- ... is different that inside the newly discovered “bifurcation phase”.

Revision of CDT basics

The transfer matrix idea and measurement

Transfer matrix in 'C' (de Sitter) phase

Transfer matrix in 'A' (uncorrelated) phase

Transfer matrix in 'B' (collapsed) phase

Conclusions and prospects

- The transfer matrix approach allows to measure the effective action directly
- The effective action inside phase 'C' is well described by the MS model
- The transfer matrix method gives access to effective action in other phases
- Inside 'A' (uncorrelated) phase the kinetic term vanishes as expected \Rightarrow possible relation to asymptotic silence ???
- Inside 'B' (collapsed) phase the structure of the transfer matrix is very nontrivial ("double-gaussian" kinetic term)
- "Double-gaussian" structure continues after crossing previously measured B-C phase transition line \Rightarrow possible existence of new "bifurcation phase" with different scaling properties (will it survive in infinite volume limit ???)
- Open questions:
 - "bifurcation" mechanism in B-C phase transition \Rightarrow possible signature change ??
 - scaling properties / critical exponents in A-C and B-C phase transitions

Thank You for attention !!!
